WHERE ARE WE?

WHERE ARE WE?

our **Universe** contains MANY billions of **galaxies**

ours is called "The Milky Way" and it contains about 1 hundred billion stars

around most of the stars are systems of planets (ours is called "**The Solar System**")

our home planet is **Earth**

Earth resides in the **Solar System**, around the **Sun**, which is one of MANY **stars**,
INSIDE the **Milky Way**,

Earth resides in the **Solar System**, around the **Sun**, which is one of MANY **stars**,
INSIDE the **Milky Way**, which is one of MANY **galaxies**, in our **Universe**

Remember, please
this SCHEMATIC diagram is
NOWHERE CLOSE to scale.

(Earth-Sun distance)/(size of Milky Way)= 6 billion

Earth resides in the **Solar System**, around the **Sun**, which is one of MANY **stars**,
INSIDE the **Milky Way**, which is one of MANY **galaxies**, in our **Universe**

And, actually, that boring blue box likely looks something more like this...

...cartoon!

...and **we** are buried **INSIDE** the Milky Way.

OK, great, I get where we are.

Why work on
“understanding the structure of the Milky Way”

Musca

Corona Australis

Chamaeleon

Above, an illustration of the Local Bubble, which formed in the Milky Way, when supernova explosions drove off all the gas and dust from a 1,000-light-year-wide region.

The team plans to go on and map more bubbles in the Milky Way fluff of champagne. There must be more, Dr. Goodman said, because it would be so much of a coincidence for the sun to be smack in the middle of the only one.

The sun's presence in this one is nonetheless coincidental, Dr. Alves said. Our star wandered into the region only five million years ago — long after most of the action — and will exit about five million years from now.

The motions of the stars are more irregular than commonly portrayed, as they are bumped gravitationally by other stars, clouds and the like, Dr. Alves said.

"The sun is moving at a significantly different velocity than the average of the stars and gas in the solar neighborhood," he noted. This would enable it to catch up and pass — or be passed by — the bubble.

"It was a revelation," Dr. Goodman said, "kooky the sun's path really is combed with a simple circle."

Local Bubble began 14 million years ago with a massive supernova, the first of about 15; massive stars died and blew up. Their blast waves cleared out the region. There are now no stars younger than 14 million years in the bubble, Dr. Goodman said.

The bubble continues to grow at about 4 miles a second. "Still, more supernovae are expected to take place in the near future, like Antares, a red supergiant star near the edge of the bubble that could go any century now," Dr. Alves said. "So the Local Bubble is not 'done.'"

With a score of well-known star-forming regions sitting on the surface of the bubble.

 Where Our Bubble Ends, Our Understanding Begins

By mapping a region devoid of gas and dust, scientists learn more about star formation.

WHERE IS THE LAST? For New Year resolutions, astronomers have discovered that the Milky Way galaxy, the home to the Sun, is not a simple disk. It is a complex, multi-layered structure. As it happens, our solar system is passing through the center of a vast, multi-million-year-old bubble of gas and dust. This bubble, known as the Local Bubble, is the result of a series of supernova explosions that have shaped the local interstellar medium. The bubble is roughly spherical and extends about 100 light-years from the Sun. It is bounded by a shell of gas and dust, which is the result of the expansion of the bubble. The interior of the bubble is mostly empty, with only a few stars and small clouds of gas and dust. The bubble is thought to have formed about 10 million years ago, when a series of supernova explosions created a cavity in the interstellar medium. The bubble is still expanding, and it is expected to continue to grow for millions of years. The study of the Local Bubble is important because it helps us understand the processes that shape the interstellar medium and the formation of stars. It also provides a window into the history of the Milky Way galaxy.

Hubble Data Story

In HubbleDS, learners use real astronomical data to answer questions like, "Has the universe always existed? If not, how long ago did it form?"

Students also learn about the scientific process, and in particular, how scientists use their data to assess how reliable their results are when it is not possible to look up answers to new questions online or in the back of a textbook.

The team is recruiting high school and college educators to use HubbleDS in their classrooms in Spring 2025 as part of the project's summative evaluation.

HOW MANY UNIVERSES ARE THERE?

This evening two California astronomers will discuss the Size of the Universe, and present their views as to whether or not there is only one or several universes, before the National Academy of Sciences, which is now in session in Washington.

In this public meeting, Dr. Harlow Shapley of the Mt. Wilson Solar Observatory, will discuss recently secured evidence pointing to the dimensions of our galaxy of stars, known popularly as the Milky Way, which he believes to be ten times greater than is held in the older theories concerning the dimensions and compositions of the Milky Way. In other words, he claims that it takes light about three hundred thousands of years to cross from one side to the other of the space occupied by the 3,000,000,000 stars of which our sun is the nearest one. He holds the spiral nebulae, those clam-shell-like cloudy luminous objects seen by great telescopes, to be inside our system.

Doctor Shapley's views will be followed by the discussion of Doctor Heber D. Curtis of the Lick Observatory, who will defend the older view that our Milky Way is approximately of the dimensions suggested by Newcomb, about 30,000 light-years in diameter, with the spiral nebulae regarded as very probably individual galaxies, of "island universes", like ours. Thus there may be a million other universes each having 3,000,000,000 stars. Inhabitants of these numerous universes would see our Milky Way as a spiral nebula. The lectures of these two learned astronomers will be followed by a general discussion open to the auditors present who are interested in the development of this new advance in scientific research.

NUMBER 1

ON THE DARK MARKINGS OF THE SKY

WITH A CATALOGUE OF 182 SUCH OBJECTS

By E. E. BARNARD

It would be unwise to assume that all the dark places shown on photographs of the sky are due to intervening opaque masses between us and the stars. In a considerable number of cases no other explanation seems possible, but some of them are doubtless only vacancies.

I do not think it necessary to urge the fact that there are obscuring masses of matter in space. This has been quite definitely proved in my former papers on this subject. If any doubt remains of this it will perhaps be readily dispelled by a close examination of the photographs previously printed. The conclusive ones I think are:

1. The photograph of the nebula about Nu Scorpii¹ which clearly shows partial and complete obscuration by the great wing-like nebula that covers much of the immediate region of Nu Scorpii and extends southward to the great nebula of Rho Ophiuchi.

2. The region of Rho Ophiuchi, where a large space of sky is blotted out by a great and beautiful nebula.² The fact of obscuration is clearly evident here, for wherever a trace of the nebula

Planetarium DataViz: OpenSpace, glue and WWT working together

handout, 2/4/2025, Boston Museum of Science: online tinyurl.com/mos-2-25-handout

Handout++

Tonight, we will demonstrate how **OpenSpace**, **WorldWide Telescope**, and **glue**, work together to **enhance the visualization of complex data sets**. The integration of these three software packages offers an exceptionally broad range of visualization, discovery, and educational opportunities. In education, **Cosmic Data Stories** uses glue and WWT together in browser-based environments to teach data science using Astronomy and Earth Science data. The **MilkyWay3D.org** project, excerpts from which you will see tonight, is a community-based effort to share everything we know and learn about the local Milky Way, to facilitate research, visualization, and outreach efforts simultaneously.

An example from MilkyWay3.org: In the image above, an inset WorldWide Telescope (WWT) view (framed in pink) shows a Spitzer image of the region marked by the pink cross in the center of the frame to the upper right. At right, extending vertically, one can see the Galactic plane, projected on the AMNH Hayden Planetarium dome, with blue hexagons displaying a catalog of HII regions available in OpenSpace thanks to Digital Universe. The model for the Radcliffe Wave is shown as a light pink wavy line at upper right is coming from the glue plug-in to OpenSpace. (Note that WWT 2D views like the one shown are only relevant when the Universe is viewed in OpenSpace in “3D” from near Earth.)

glue viewer with multiple datasets from the MilkyWay3D, ready to be viewed in OpenSpace

OpenSpace in the AMNH Hayden Planetarium showing young stars, molecular clouds, with a WorldWide Telescope view of the green-boxed area

A “console” view on a laptop, controlling OpenSpace, glue, and WWT simultaneously. Only visible to the planetarium operator.
